

Switch Case Statement in Java: -

In Java, the “**switch**” statement is a control flow statement that allows you to select one of many code blocks to be executed based on the value of a variable or expression.

It provides a convenient way to write multiple conditional statements in a more concise and readable manner.

How Does the Switch Case Statement Works?

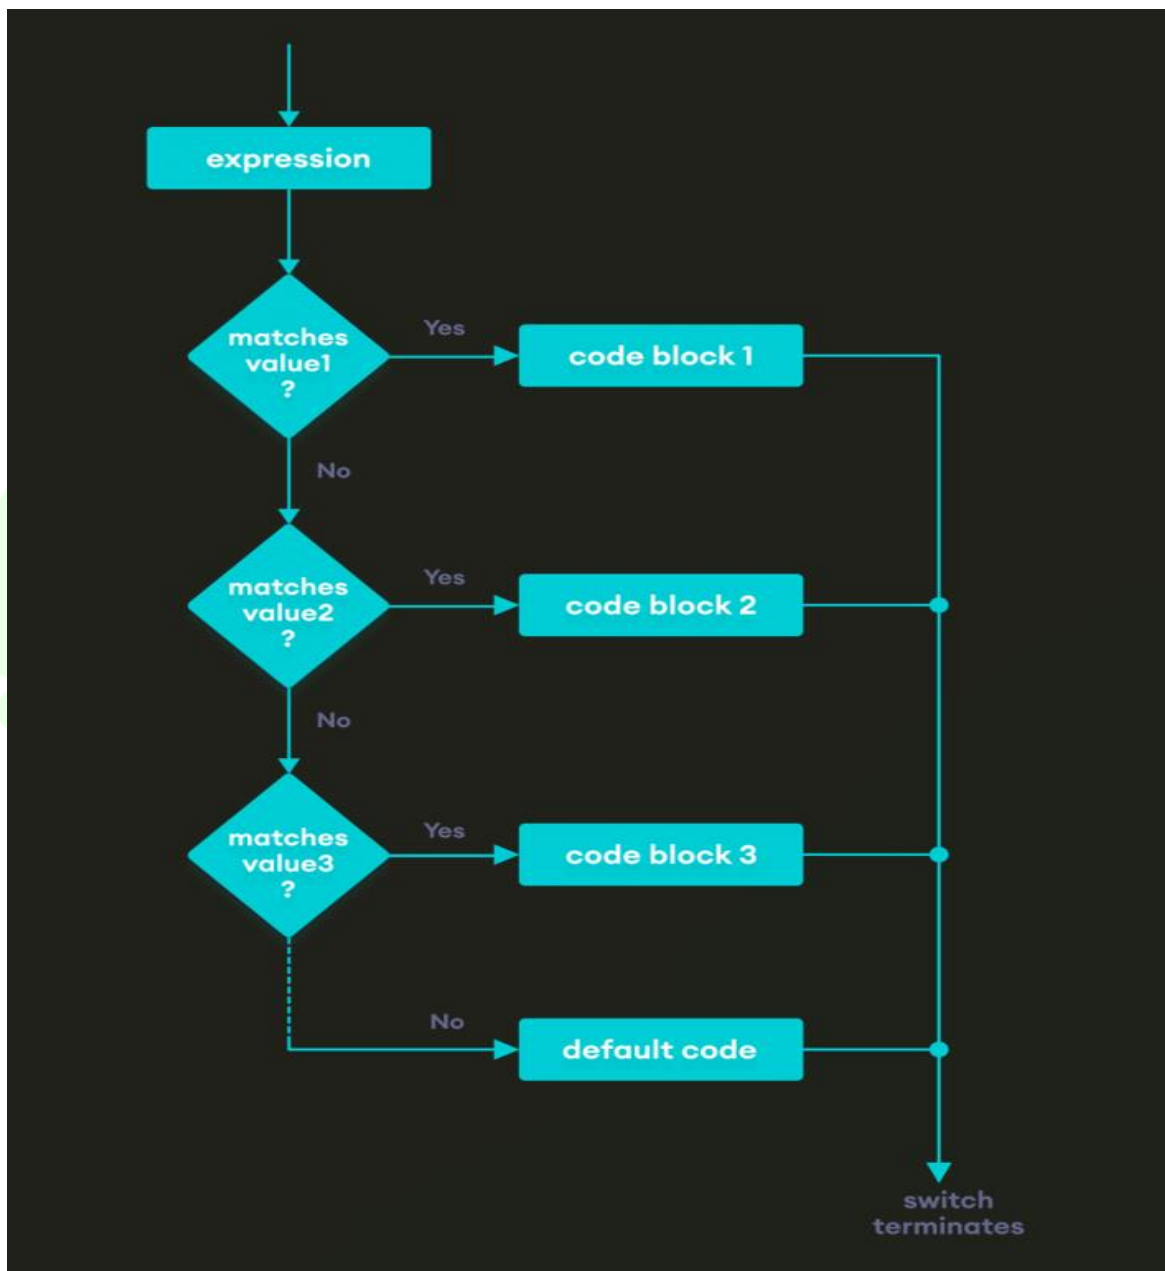

The expression is evaluated once and compared with the values of each case.

- If **expression** matches with **value1**, the code of **case value1** are executed.
- Similarly, the code of case value2 is executed if expression matches with value2 and so on.
- If there is no match, the code of the **default case** is executed.

Flow Chart of Switch Case Statement:

Switch case statement flow chart is given below-

Syntax of Switch Case Statement:

```
switch (expression) {  
  
    case value1:  
        // code block to be executed if expression matches value1  
        break;  
  
    case value2:  
        // code block to be executed if expression matches value2  
        break;  
  
    case value3:  
        // code block to be executed if expression matches value3  
        break;  
    .  
    .  
    .  
    .  
    // more cases...  
  
    default:  
        // code block to be executed if expression does not match any  
        // of the cases  
  
}
```

The Break Keyword in Switch Case:

- Break statements are used when you want your program-flow to come out of the switch body.
- Whenever a break statement is encountered in the switch body, the execution flow would directly come out of the switch, ignoring rest of the cases.

The Default Keyword in Switch Case:

- The default keyword specifies some code to run if there are no cases match.
