Essential to use axios: -

1. URL (API): -
2. Method Type: -
3. Data Format: -

Axios provide below methods to do network calls.

- 1> get()
- 2> post ()
- 3> put()
- 4> delete()
- 5> patch()

We can pipeline then() method and catch() method on them. To extract the response.

then() method: - then method is use to extract success response of the API request. Then method accepts parameter argument as callback function. Call back function will receive the success response as it's parameter argument.

catch() method: - catch method is use to extract error response of the API request.

Example of Axios get() method: -

JS ViewEmployee.js U X

src > component > view-employee > JS ViewEmployee.js > ViewEmployee > onGetData

```
1  import './ViewEmployee.css'
2  import axios from 'axios';
3  import { useState } from 'react';
4  function ViewEmployee()
5  {    // []
6      const [employees,setEmployees]= useState([]);

9      //event handler:- a js fuction which is invoke to handel the
10     // event is call envent handler
11     function onGetData()
12     {

14         axios.get('http://localhost:9090/getemployees').then(
15             function (response)
16             {
17                 setEmployees(response.data)
18                 console.log(response.data)
19             }
20         ).catch(
21             function (error)
22             {
23                 if(error.response.status===500)
24
25                 {
26                     alert("Something went wrong..!")
27                 }
