

Quick Overview To The JavaScript

Java Script Functions: -

In JavaScript functions are nothing but reusable blocks of code, design to perform particular task. functions are used to organize the code.

JavaScript functions are need to be invoke. we can also invoke them using html event to.

In JavaScript there are 3 ways to define function.

1. Function Declaration (Traditional approach).
2. Function expression.
3. Arrow function (ES6).

1. Function Declaration: -

JavaScript traditional functions are declared using function keyword, and mediately followed by function name.

Example: -

a) Simple JS function: -

```
function add()  
{  
    let x=100;  
    let y=200;  
    let result=x+y;  
    console.log(`Addition of ${x} and ${y} is :- ${result}`)  
}  
// function call  
add();
```

b) Parametrize JS function: -

```
function sub(x,y)
{
    let result=x-y;
    console.log(`Substraction of ${x} and ${y} is :- ${result}`);
}
//function call
sub(500,300);
```

c) JS function with return statement: -

```
function mul()
{
    let a=10;
    let b=2;
    console.log(`Multiplying ${a} and ${b}`)
    let result=a*b;

    return result;
}
// function call
let result= mul();
console.log("Mulplication Result is :- "+result);
```

Task: - Create One function declaration with name `divide` which should accept two parameter argument and should return the result of division.

2. Function Expression: -

In function expression function name is omitted and the function is assigned to the variable. They can be pass as a argument to another function.

a) Simple JS function Expression: -

```
const instituteName = function () {  
    console.log("Complete Java Classess, By Kunal Sir.");  
}  
//function call  
instituteName();
```

b) Parametrize JS function Expression: -

```
const getLength = function (name)  
{  
    let lengthOf=name.length  
    console.log(`String ${name} contains ${lengthOf} characters.`);  
}  
getLength("cjc")
```

c) JS function Expression with return statement: -

```
const getDate =function()  
{  
    let date=new Date();  
    return date;  
}  
let todayDate=getDate();  
console.log("Today's date is:- "+todayDate);
```

3. Arrow functions: -

Arrow functions are the new approach to define function in JavaScript. Arrow functions are used to con-size the code.

They are quite similar to the java lambda expression.

Arrow functions are denoted by `=>` symbol.

Arrow function are introduce to replace the function expressions.

```
console.log("-----Arrow functions-----")

const fun    =    ()=>{
  console.log("Pratik");
  console.log("CJC")
}
fun();

const add1=(a,b)=>console.log(`Addition of ${a} and ${b} is : ${a+b}`)

add1(10,20)

const subtraction= (x,y)=> x-y;

let subResult=subtraction(50,10);

console.log("Result Of Substraction :- "+subResult);
```

Sorting using Arrow Functions: -

```
const u1={
  username:"pqr",
  age:19
}
const u2={
  username:"xyz",
  age:18
}
const u3={
  username:"abc",
  age:31
}

const users=[u1,u2,u3]
console.log(users);
// users.sort()

console.log("Sort By Username :- ")
users.sort((u1,u2)=>u1.username.localeCompare(u2.username));
console.log(users);

console.log("Sort By Age:- ")
users.sort((u1,u2)=>u1.age-u2.age);
console.log(users);
```

Conditional Statements: -

In our program, some time we need to perform different actions on different values, at that time conditional statements are used to implement those conditions in our program.

Below are the conditional statements available in JavaScript.

1. if statement.
2. else statement.
3. else if statement.
4. switch statement.

Example:-

```
function ageValidator(age)
{
    if(age>=21)
    {
        console.log("Valid Age To Apply Driving License...!")
    }
    else if(age<=20 && age>=18)
    {
        console.log("Valid Age To Apply learning license")
    }
    else{
        console.log("Better luck next time..!")
    }
}
```

by Kunal Sir

```
ageValidator(10);

function getFees(course)
{
    switch(course){

        case 'Java' : console.log("You have selected Java.")
                      console.log("Fees is 27000")
                      break;

        case 'Python' : console.log("You have selected Python.")
                       console.log("Fees is 25000")
                       break;

        case 'React' : console.log("You have selected React.")
                      console.log("Fees is 10000")
                      break;

    }
}

getFees('Python')
```
